

Run simulation from Icarus (Verilog):

1. `cd "C:\iverilog\Verilog_Basics"` // cd
2. `iverilog -o and_gate_tb and_gate.v and_gate_tb.v` // compile
3. `vvp and_gate_tb` // start simulation
4. `and_gate.vcd` // creates output storage file
5. `C:\iverilog\gtkwave\bin\gtkwave.exe and_gate.vcd` // executes GTK and .vcd file
simultaneously

Where does `and_gate.vcd`, `and_gate_tb`, and `uut` (defined inside `and_gate_tb`) go?

If step 2 doesn't work, then possibly we didn't add the paths as environmental variables so execute this to add them automatically:

- 1) `setx PATH "%PATH%;C:\iverilog\bin;C:\iverilog\gtkwave\bin"`

Push to github (Enter these commands in CMD Prompt):

- `git init`
- `git add .`
- `git commit -m "Initial release of UART Communication Engine"`
- `git branch -M main`
- `git remote add origin https://github.com/YourUsername/UART_Communication_Engine.git`
- `git push -u origin main`

Personally, I prefer to drag and drop because it's more efficient for me, but it's always good to know the different ways to use the command prompt!
